ABSTRACT

Recommender system is an essential part of any social media application. Most recommender systems now use a hybrid approach, combining collaborative filtering, content-based filtering, and other approaches. Most common problems in the field of hybrid recommenders are cold start and data sparsity [Çano, 2017]. In this paper we address the abovementioned problems by proposing a hybrid weighted news recommender system which combines different approaches.

Keywords hybrid recommender systems · content-based recommender · collaborative recommender · optimizations

1 Introduction

Recommender system is a crucial part of every application that operates with content and user activity. Enormous amount of information leads to the problem that user is not able to find relevant content.

Common approaches, such as collaborative filtering, has its own problems: cold start, scalability and data sparsity. Content-based approaches suffer from the fact that we have to somehow represent recommended item in feature space.

To be consistent during the paper we list some domain specific vocabulary with their meanings:

- Rating: expression or preference
 - explicit (direct from user, e.g. user rated film)
 - implicit (inferred from user activity, e.g. user stopped watching movie after 5 minutes)
- Prediction: estimate of preference
- Recommendation: selected items for user
- Content: attributes, text, etc; everything about item

The remainder of this paper is organized as follows:

- Section 2 describes the relevant related work
- Section 3 describes input data
- Section 4 explains our modular design and architecture
- Section 5 describes the implementation of the algorithms in a real system
- Section 6 provides tests and experiments validating our systems results
- Section 7 explains future work
- Section 8 presents conclusions

4 Overview of our approach

Out goal is to combine state-of-the-art approaches in recommender systems.

According to the study [Dacrema et al., 2019], deep learning techniques are not supposed to beat conceptually and computationally simpler algorithms, so we won't touch them.

Our approach consists of combining several techniques:

- Collaborative filtering:
- Content-based filtering:
- Session filtering:
- Popularity filtering:
- Demographic filtering:
- Time-based filtering:

Solution consists of 2 parts:

- Candidate generation
- Ranking

4.1 Collaborative filtering recommendation

For collaborative filtering recommendation we should have something known as user-item matrix which may be formed from user activity from tables (cite tables)

4.2 Popularity-based recommendation

For measuring news item popularity following data can be aggregated: shows, views, emotions, comments.

item_id	shows_num	views_num	emotions_num	comments_num
1	1043	231	52	7
2	828	478	78	11
3	163	25	5	0
:	÷	÷	÷	:

Table 8: aggregated popularity data

- 5 Implementation
- 6 Evaluation
- 7 Further research
- 8 Summary

Results show that combining different approaches leads to rise of users' involvement.
